54	HYDROCARBON SYNTHESIS PROCESS USING A HYDROCARBON SYNTHESIS CATALYST AND AN ACIDIC CATALYST			

HYDROCARBON SYNTHESIS PROCESS USING A HYDROCARBON SYNTHESIS CATALYST AND AN ACIDIC CATALYST

Technical Field

This invention relates to a hydrocarbon synthesis process and more particularly to such a process wherein a hydrocarbon synthesis catalyst and an acidic catalyst is used. The process is particularly, but not exclusively, suitable for producing liquid fuel. The process is also suitable for producing hydrocarbons rich in aromatics such as benzene, toluene and xylenes or hydrocarbons rich in branched hydrocarbons or rich in olefins.

Background Art

Fischer-Tropsch processes for hydrocarbon synthesis from CO and H₂ (syngas) are known to produce gaseous and liquid hydrocarbons as well as oxygenates which, in general, follow the well-known Anderson-Schulz-Flory product distribution.

These reactions can be carried out in fixed, fluidised or slurry bed reactors. The production of olefins and liquid fuels, especially in the gasoline range products, is most favoured by synthesis carried out in a two-phase fluidised bed reactor operating at 350°C and 20 bar or higher pressures and usually utilizing a fused alkali promoted iron catalyst. This is known as a high temperature Fischer-

Tropsch process.

In terms of the ideal Anderson-Schulz-Flory product distribution it is clear that the gasoline (C_5 to C_{11}) and diesel (C_{12} to C_{18}) selectivities are limited to values of about 48% and 25% respectively, while combined liquid fuels selectivity has a maximum value of around 65%. In a high temperature Fischer-Tropsch process performed in a fluidised bed reactor, the optimum liquid fuel yield might not be realised, thus resulting in a lower liquid fuel selectivity. In addition to this relatively low liquid fuel yield, the Fischer-Tropsch process has a further disadvantage in that the product spectrum mainly consists of linear hydrocarbons. This is a disadvantage with respect to gasoline quality, since linear molecules have a very low octane number. Fischer-Tropsch gasoline thus requires either further work-up to convert the product to one with a higher octane number, or the addition of high-octane compounds to the gasoline pool.

It is known that the Fischer-Tropsch product spectrum can be worked-up to high octane gasoline range fuels by using an acidic catalyst such as a zeolite catalyst. Such a work-up has the disadvantage that it adds to the production costs of the liquid fuel.

In order to reduce the above disadvantage it has been attempted to combine a Fischer-Tropsch catalyst with a zeolite catalyst in order to prepare high octane gasoline range fuels directly from CO and H_2 . In such a system the idea is that the Fischer-Tropsch catalyst should catalyse the conversion of CO and H_2 to

hydrocarbons, and the acid catalyst should convert the resulting olefinic and oxygenated hydrocarbons to gasoline range products that are highly branched and high in aromatics.

US 4 086 262, US 4 279 830, US 4 361 503, US 4 269 783, US 4 172 843, US 4 446 3101, US 4 298 695, US 4 304 871, US 4 556 645, US 4 652 538 all disclose the combined use of a hydrocarbon synthesis catalyst and an acidic catalyst in the preparation of hydrocarbons from syngas. The two catalytic functions have been combined in a variety of ways, ranging from a single reactor containing both catalytic functions to a dual reactor arrangement with the two catalytic functions in subsequent reactors. Different reaction conditions and different catalysts are disclosed in these patents.

It is recognised (eg. US 4 298 695) that the addition of alkali promoters to the iron based Fischer-Tropsch catalyst in a bi-functional process (Fischer-Tropsch catalyst and acidic catalyst) is undesirable, since these promoters tend to migrate to the acidic catalyst with a resultant poisoning of the acid sites. However, it is known that iron based Fischer-Tropsch catalysts with a low alkaline promoter level tend to produce light hydrocarbons that are not desirable for gasoline production since they do not fall in the gasoline range of C_5 to C_{11} and are also not easily converted to this range.

Therefore, should a low level of alkali promoter be considered in the production of liquid fuel from syngas, the reaction conditions would be selected to produce

a heavier hydrocarbon product despite the low alkali level. It is well-known that a high H_2 : CO ratio in the feed favours products which are not desirable for gasoline production. Accordingly if a low level of alkali promoter is considered a relatively low H_2 : CO ratio in the feed will be considered to avoid production of excessively light hydrocarbons.

Surprisingly it has now been found that if hydrocarbon synthesis of syngas is carried out in the presence of a hydrocarbon synthesis catalyst and an acid catalyst under conditions where:

- i) the hydrocarbon synthesis catalyst includes a low level of alkali; and
- ii) the hydrogen to carbon monoxide ratio of the syngas feed stream is relatively high,

a hydrocarbon product is produced that is suitable for use as gasoline. This is true even if the synthesis is carried out under high temperature Fischer-Tropsch conditions.

Disclosure of the Invention

According to the present invention there is provided a hydrocarbon synthesis process comprising the conversion of H_2 and at least one carbon oxide in syngas to hydrocarbons containing at least 30% on a mass basis C_{5+} compounds, the hydrocarbon synthesis process being carried out in the presence of an alkali-promoted iron hydrocarbon synthesis catalyst and an acidic catalyst suitable for converting hydrocarbons; the process being

characterised therein that the reaction mixture of the feed contains less than 0.02 mol alkali per 100g iron and that the H_2 : carbon oxide molar ratio in the feed is at least 2.

The synthesised hydrocarbon product preferably contains, on a mass basis, at least 35%, more preferably at least 40% and most preferably at least 50%, C_5^+ compounds. Preferably, the process is for producing liquid fuel, especially gasoline and preferably unleaded gasoline. The process may also be used for producing hydrocarbons rich in aromatics such as benzene, toluene and xylenes and/or hydrocarbons rich in branched hydrocarbons and/or rich in olefins.

The hydrocarbon synthesis process may comprise a Fischer-Tropsch process, preferably a high temperature Fischer-Tropsch process. The temperature range may be between 250°C and 400°C, typically from 300°C to 370°C, and even from 330°C to 350°C. The pressure may be from 10 to 60 bar (1 to 6 MPa), typically from 15 to 30 bar, and usually at about 20 bar.

The at least one carbon oxide in the syngas preferably comprises CO.

The reaction may be carried out in any suitable reactor. It is foreseen that it will be carried out in a fluidised bed reactor, preferably in a fixed fluidised bed reactor. If the CO hydrogenation function and the acid catalyst function are contained on separate particles, the invention is especially suited to a fluidised

bed reactor, since there will not be extensive direct contact between the different catalysts which will reduce migration of the alkali promoters from the hydrocarbon synthesis catalyst to the acidic catalyst, thereby reducing the detrimental results associated with such migration.

In another embodiment of the invention there is provided a hydrocarbon synthesis process comprising the conversion of H_2 and at least one carbon oxide in syngas to hydrocarbons containing at least 30% on a mass basis C_{5+} compounds, the hydrocarbon synthesis process being carried out in a fluidised bed reactor in the presence of a hydrocarbon synthesis catalyst and an acidic catalyst suitable for converting hydrocarbons.

The hydrocarbon synthesis catalyst may comprise any suitable alkali-promoted iron catalyst suitable for CO hydrogenation but preferably it comprises a Fischer-Tropsch catalyst. The iron catalyst may comprise a precipitated iron catalyst or a fused iron catalyst. If the process is to be performed in a fluidised bed reactor, the final catalyst may be produced by means of a variety of known methods in order to obtain particles with acceptable fluidisation properties, such as crushing, spray-drying, etc. In order to obtain a particle size distribution suitable for fluidisation, the catalyst may be classified by means of known methods, such as sieving, cyclone classification, etc.

The iron catalyst contains at least one alkali promoter usually in the form of an alkali oxide. The alkali promoter preferably comprises potassium or sodium

oxide. The catalyst may contain more than one alkali promoter. The alkali can be added to the iron by means various methods, such as impregnation of the iron with the alkali, co-precipitating the alkali with the iron, fusing the iron and the alkali, etc. The total alkali content (mol alkali per 100 g iron) must preferably be below 0.02, more preferably below 0.01, and most preferably below 0.005.

The iron catalyst may also contain other promoters. Certain promoters, for example Al, Ti, Cr, Mg, Mn and Ca can be added as structural promoters to the iron catalyst. Binders, such as silica or alumina, may also be added in case of a spray-dried catalyst.

The acidic catalyst may comprise a zeolite. The zeolite may comprise a HZSM-5 zeolite. If the process is to be performed in a fluidised bed, the final acid catalyst may be prepared in any suitable known way in order to obtain particles with acceptable fluidisation properties. For example, the acid catalyst may be a spray-dried catalyst. A binder (such as silica or alumina) may also be added to the acidic catalyst.

The silica / alumina ratio of the zeolite can be varied according to the product spectrum desired and the lifetime required for the catalyst.

The hydrocarbon synthesis catalyst and the acidic catalyst may be combined in a variety of ways. It is foreseen that in a preferred embodiment of the invention the two catalysts will be contained on separate particles and preferably contact

between the particles containing the different catalysts should be limited. This will reduce migration of the alkali promoter to the acidic catalyst. However, it may also be possible to combine the two catalysts into particles containing both catalytic functions. For example, the two catalysts may be pressed into pellets or spray-dried to produce particles that contain both catalytic functions. The hydrocarbon synthesis catalyst may also be supported by the acidic catalyst. The iron may be loaded onto the acidic catalyst by means of a variety of art-recognised methods, such as precipitation, impregnation, chemical vapour deposition, ion exchange, etc.

The ratio (by mass) of hydrocarbon synthesis catalyst to acidic catalyst is preferably at least 1, more preferably higher than 4.

The synthesis feed gas may also include other components, such as water vapour, Ar, CH₄, light hydrocarbons, etc.

The hydrocarbon products of the process may comprise mainly of branched paraffins and olefins, cyclic paraffins and olefins, and aromatics, but linear paraffins and olefins may also be present in the product spectrum.

The invention also relates to hydrocarbons produced by the process substantially as described hereinabove.

The invention will now be further described by means of the following non-

limiting examples.

Examples

Catalysts

A fused iron catalyst containing low levels of alkali was employed as the syngas conversion function. The catalyst was prepared by adding the relevant promoters to oxidised mill-scale to obtain a dry mixture of the precursor material. This mixture was then fused in an electric arc furnace at a temperature of about 1650°C. The molten material was cast as ingots. After cooling, the ingots were crushed, milled and then sieved to obtain a particle size fraction of 38 to 150 micron. The composition of the catalyst is presented in Table 1.

Table 1: Composition of fused iron catalyst

Component	Concentration
Fe (mass %)	70.8
K (mol / 100 g Fe)	0.0064
Na (mol / 100 g Fe)	0.0113
SiO ₂ (g / 100 g Fe)	0.78
Al ₂ O ₃ (g / 100 g Fe)	0.32

Both K and Na were in the form of their oxides namely K_2O and Na_2O .

The acidic catalysts comprised a "high alumina content" HZSM-5 zeolite (SiO_2/Al_2O_3 molar ratio of 30) and a "low alumina content" HZSM-5 zeolite (SiO_2/Al_2O_3 molar ratio of 280) supplied by Zeolyst International. The Zeolyst product numbers of the zeolites are CBV3024E and CBV28014 for the "high alumina content" and "low alumina content" ZSM-5 zeolites, respectively. The zeolites were in the powdered form and were used as such for the purpose of the microreactor experiments. The zeolites were supplied in the ammonium form (NH_4 ZSM-5) and prior to use they were calcined in air at a temperature of $500^\circ C$ for 16 hours to convert them to the acidic form (HZSM-5).

Reactor System

A Berty microreactor was used. The catalyst inside a Berty microreactor is contained in a very thin bed. A fan, situated below this bed, circulates gas through the catalyst at a high rate. The reactor can therefore essentially be viewed as a short packed bed with an extremely high recycle ratio, and thus behaves approximately like a continuous stirred tank reactor (CSTR). Since the gas circulation through the catalyst ensures that there are no significant temperature or concentration profiles across the bed, this reactor is ideal for studying the highly exothermic high temperature Fischer-Tropsch (HTFT) reaction.

The main component of the Berty reactor feed during the examples was a commercial synthesis gas stream. Pure hydrogen and carbon dioxide were co-fed from bottles in order to obtain a total syngas feed to the Berty reactor that was rich in hydrogen. In addition, bottled argon was fed to the reactor, which served as an internal standard. The flow rates of the four feed streams were controlled by Brooks mass flow controllers. The composition of the total Berty feed is presented in Table 2.

Table 2: Feed stream composition of Berty reactor experiments (volume %)

<u>Component</u>	<u>Volume %</u>
H ₂	58
CO	12.5
CO ₂	12
CH ₄	5.5
Ar	12

The effluent from the Berty reactor was passed through a two-stage knock-out system. In the first pot (hot knock-out pot), waxy hydrocarbons were condensed. The amount of product drained from this pot, if any, was negligible.

A second pot (cold knock-out pot) condensed the condensable hydrocarbons and reaction water, while the uncondensed effluent flowed to a vent system.

The product sampling point was situated before the cold knock-out pot to ensure that a sample was taken of the comprehensive product spectrum. Samples were taken in glass ampoules for later GC analysis. The hydrocarbon product spectrum was characterised by means of a GC-FID analysis.

Loading of the reactor

At the start of the experimental investigation, a baseline high temperature Fischer-Tropsch run was performed with 5 g of iron catalyst (unreduced weight).

The process runs according to the invention was performed with 5 g of iron catalyst and 5 g of "high alumina content" HZSM-5 zeolite in the one case and 5 g of iron catalyst and 5 g of "low alumina content" HZSM-5 zeolite in the other case. In both cases an iron catalyst layer was loaded on top of a zeolite layer and the layers were separated by a fine wire mesh thereby avoiding contact between the catalysts.

Catalyst activation and synthesis

The zeolites did not require any additional activation. The iron catalyst was reduced with a hydrogen feed of 1000 ml/min for 16 hours at a temperature of 420°C prior to synthesis. Thereafter, the temperature was lowered to 330°C under a combined feed of argon and hydrogen. After the temperature had stabilised, synthesis commenced by setting all the mass flow controllers to the

desired values in order to obtain the total feed composition presented in Table 2 at a total flow rate of 1500 ml/min . During reduction and synthesis, the total reactor pressure was maintained at 20 bar.

Results

The results of the experiments are presented in Table 3. The product obtained from the process contains a vast number of components. However, only certain compounds that were unambiguously identified were presented to illustrate the benefits of combining an iron catalyst and an acid catalyst according to the invention.

From the results it is clear that the process according to the invention produced a substantial amount of condensable hydrocarbons, even though the syngas feed to the reactor was rich in hydrogen and the alkali content of the iron catalyst was low. The C_5^+ selectivity was about 50 % for both examples of the process according to the invention.

It is further clear that the addition of an acidic catalyst to the Fischer-Tropsch process increased the selectivity of the condensable hydrocarbons. The selectivity of the C_5^+ hydrocarbons increased significantly, especially in the case of the "low alumina content" HZSM-5. The increase in the C_5 to C_{11} fraction, which contains most of the gasoline range components, was even more substantial.

The results also indicate that the normal Fischer-Tropsch product consists mainly of linear hydrocarbons and contains little aromatic and branched compounds. Since linear hydrocarbons have a very low octane value, they are undesirable as gasoline components. By adding an acid catalyst to the process, the amount of aromatics in the product increased dramatically and the paraffins and olefins became substantially more branched. These effects are especially noted for the case of the "high alumina content" HZSM-5.

The examples presented therefore clearly illustrate that the addition of an acidic catalyst to the Fischer-Tropsch process not only increases the selectivity of compounds that fall inside the gasoline range, but also that an improved gasoline fraction, containing substantially higher amounts of high octane value compounds such as aromatics, branched paraffins and branched olefins, is produced.

TABLE 3: Results
